**PIN CONFIGURATION**

Pin Number	Description
1	Regulating voltage : information input concerning secondary voltage. By comparing the regulating voltage obtained from the regulating winding of the transformer with the internal reference voltage, the output pulse width on Pin 5 is adapted to the load of the secondary side (normal, overload, short circuit, no load)
2	Primary current simulation : information input regarding the primary current. The primary current rise in the primary winding is simulated at Pin 2 as a voltage rise by means of external RC element. When a value is reached that is derived from the regulating voltage at Pin 1, the output pulse at Pin 5 is terminated. The RC element serves to set the maximum power at the overload point.
3	Primary voltage detector : input for primary voltage monitoring. When the line voltage is too low the IC is switched-off by comparing $V_3$ with an internal reference. Voltage at Pin 3 is used for overload point compensation.
4	Ground
5	Output : push-pull output for charge and discharge of the gate capacitance of the power MOS transistor.
6	Supply voltage : Supply voltage input. From it are derived a stable internal reference voltage ( $V_{REF}$ ) and the switching threshold $V_{6A}$ , $V_{6E}$ , $V_{6\ max}$ and $V_{6\ min}$ for the supply voltage detector. if $V_6 > V_{6E}$ the $V_{REF}$ is switched on and switched off when $V_6 < V_{6A}$ . In addition the logic is only enable for $V_{6\ min} < V_6 < V_{6\ max}$ .
7	Soft-start : input for soft-start and integration network. Start-up will begin with short pulses by connecting a capacitor between Pin 7 to ground. This capacitor together with a resistor connected between Pin 7 and error amplifier output also as acts an integrator network for regulation.
8	Zero detector : Input for the oscillator feedback. After starting oscillator, every zero transit of the feedback voltage (falling edge) triggers an output pulse at Pin 5. The trigger threshold is at typically - 50mV

## FUNCTIONAL DESCRIPTION

In free running fly-back converters, the TDA4605 assumes control of a MOS power transistor and all necessary regulation and monitoring functions.

The serial circuit of power transistor and primary winding of the flyback transformer is connected to the input voltage. During the switch-on period of the transistor, energy is stored in the transformer and during the switch-off period it is fed to the load via the secondary winding. By varying the switch-on time of the power transistor, the IC controls each portion of energy transferred to the secondary side such that the output voltage remains nearly independent of load variations.

The required control information is taken from the input voltage during the switch-on period and from a regulation winding during the switch-off period. A new cycle begins as soon as the energy stored in the transformer has been totally delivered to the secondary side.

In different load ranges, the SMPS will behave as follows:

- **No-Load Operation:** The power supply unit oscillates in non continuous mode at a typical frequency of 20 to 40kHz. Depending upon the transformer winding and the regulated voltage divider, the output voltage can be slightly above the nominal value.
- **Normal Operation:** Starting from typ. 200kHz, the switching frequency falls with increasing load and decreasing AC voltage. The duty cycle depends primarily on the AC voltage. The output voltage is only slightly load-dependent.
- **Overload Point:** Maximum output power is available at this point of the output characteristics
- **Overload:** The energy transferred per operation cycle is limited at the top. Therefore, the output voltage will fall with secondary overloading.
